

# Functions and Applications of Machine-Splitting Optical Cables

## Overview

They are devices that split an incident light beam into several light beams at certain splitting ratios. The role of these splitters in optical networks is crucial as they allow a single optical signal to be shared among many users, thereby enhancing the efficiency and capacity. An optical splitter is a crucial passive fiber optic device that splits and combines optical signals. It can distribute the optical energy transmitted through a single fiber to two or more fibers in a predetermined ratio or combine the optical energy from multiple fibers into one fiber. With their powerful signal distribution capabilities and cost-effectiveness, they have become an indispensable part of modern networks. Unlike active devices (which require power), splitters operate without electricity, relying solely on the physics of. An Optical Splitter, also known as a beam splitter, is a passive optical device that divides a single input optical signal into two or more output signals. In Passive Optical Networks (PON).
