

Outdoor server rack air duct heat dissipation principle

Overview

At the heart of server rack cooling is a basic principle: heat moves from hot to cold. This process, called thermal transfer, is how your equipment gets rid of excess heat. Rack mount equipment generates heat as a result of the processes it completes; the amount of heat a piece of equipment dissipates is approximately equal to the total electrical power delivered to it. This heat is absorbed by the ambient air in the server, and removed by airflows generated by fans. Because data centers are high-density enclosed spaces that generate a significant amount of heat, traditional comfort cooling systems can't remove enough heat to protect the critical equipment. Additionally, well-managed heat control helps systems consume less power. IT system energy efficiency. Whether you're operating industrial automation systems with electrical switchgear or high-density data servers in server racks, effective temperature management is crucial for long-term performance and equipment longevity.
