

Unequal-division FBT optical splitter

Overview

An FBT (Fused Biconical Taper) splitter is made by fusing and tapering two or more optical fibers. By changing the evanescent field coupling between the fibers (coupling degree, coupling length) and the fiber core radius, different branching ratios can be achieved. Developed in the 1980s, FBT splitters have evolved to support modern telecommunications demands, from fiber-to-the-home. A fiber-optic splitter, also known as a beam splitter, is based on a quartz substrate of an integrated waveguide optical power distribution device, similar to a coaxial cable transmission system. The optical network system uses an optical signal coupled to the branch distribution. Unlike active devices (which require power), splitters operate without electricity, relying solely on the physics of. At its core, an FBT splitter is a passive optical device that takes a single optical input signal and divides it into two or more output signals.

- The FBT splitter offers low cost, common materials (quartz substrate, stainless steel, fiber, hot dorm, GEL), and an adjustable splitting ratio. However, its losses are wavelength-dependent and it offers poor spectral uniformity, cannot ensure uniform spectroscopy, and is temperature sensitive.
- PLC splitter: Losses are not sensitive to the wavelength, spectral uniformity is higher and it is more compact and has lower cost with greater degrees of splitting. However, device fabrication process is more complex.
